The lifecycle of an object in object-oriented programming (OOP) involves the creation and destruction of objects.

These areas are uniquely addressed by constructors and destructors, which are special member functions in languages like C++ and others.

Construction of Objects:

1. Constructor:

- Any time a new object of the class is created, a constructor is automatically called.
- It initializes the state of the object, allocates resources and carries out some setup tasks that may be necessary.
- Constructors do not have any return type, but they bear the name of their class.

C++

```
class MyClass {
public:
    // Constructor
    MyClass() {
        // Initialization code goes here
        cout << "Constructor called!";
    }
};</pre>
```

2. Default constructor:

- If you don't write a constructor for your class, the compiler will make one for you.
- Such automatic constructor creates an object with default values or uninitialized

members according to their types.

C++

```
class MyClass {
    // No explicit constructor, so a default constructor is provided
by the compiler
};
```

- 3. Parameterized Constructor:
 - Constructors can take parameters, allowing you to initialize the object with specific values.

C++

```
class Point {
public:
    // Parameterized constructor
    Point(int x, int y) : xCoord(x), yCoord(y) {
        cout << "Parameterized constructor called!";
    }
private:
    int xCoord;
    int yCoord;
};</pre>
```

Destruction of Objects:

1. Destructor:

A destructor is a special member function called when an object goes out of scope or is explicitly deleted, and it is used to release resources, perform cleanup and deallocate memory.

```
C++ 

class MyClass {
    public:
        // Constructor
        MyClass() {
            cout << "Constructor called!";
        }
        // Destructor
        ~MyClass() {
            // Cleanup code goes here
            cout << "Destructor called!";
        }
    };
</pre>
```

2. Automatic Destruction:

At the end of a function, for example when an object goes out of its scope, its destructor is called automatically.

```
C++ ↓
void someFunction() {
    MyClass obj; // Constructor called
    // obj goes out of scope here, and its destructor is automatically
    called
    // Destructor called
  }
```

3. Manual Destruction:

The 'delete' keyword can be used to manually delete a dynamic object.

```
C++ ↓
Void anotherFunction() {
    MyClass* objPtr = new MyClass(); // Constructor called
    delete objPtr; // Destructor called
}
```
