

Q. How String can be concatenate in Python ? Is there any functions like C and C++ ?

Ans.

First see how concatenation in C:

C programming having strcat() for string concatenations.

See the example:

```
void main()
{
    char str1[MAX],str2[MAX];
    printf("Input string 1: ");
    gets(str1);
    printf("\nInput string 2: ");
    gets(str2);
    strcat(str1,str2);
    printf("\nConcatenated string : ");
    puts(str1);
    return 0;
}
```

Concatenation in C++:

'+' operator can be used for string concatenation.

See the example:

```
void main()
{
    string firstName = "Kunal ";
    string lastName = "Batra";
    string fullName = firstName + lastName;
    cout << fullName;
```

```
}
```

'Append()' can also be used for string concatenation:

See the example:

```
void main()
```

```
{
```

```
string firstName = "Kunal";
```

```
string lastName = "Batra";
```

```
string fullName = firstName.append(lastName);
```

```
cout << fullName;
```

```
}
```

Concatenation in Python:

'+' operator is used for string concatenation:

```
firstName = "Kunal"
```

```
lastName = "Batra"
```

```
fullName = firstName + lastName
```

```
print(fullName)
```

From above article its easy to find out the answer of the question.
